

System.Object class

What

- › The "System.Object" is a pre-defined class, which is the "Ultimate super class (base class)" in .net.
- › All the classes and other types are inherited from System.Object directly / indirectly.

```
System.Object Class [Pre-defined]

namespace System
{
    class Object
    {
        virtual bool Equals( object value );
        virtual int GetHashCode( );
        Type GetType( );
        virtual string ToString( );
    }
}
```

› **bool Equals(object value)**

- › Compares the current object with the given argument object; returns true, if both are same objects; returns false, if both are different objects.

› **int GetHashCode(object value)**

- › Returns the a number that represents the object. It is not guarantee that the hash code is unique, by default.

› **Type GetType()**

- › Returns the name of the class (including namespace path), based on which, the object is created.

› **string ToString()**

- › By default, it returns the name of the class (including namespace path), based on which, the object is created.
- › It is virtual method, which can be overridden in the child class.

- › All C# classes, structures, interfaces, enumerations are children of System.Object class.
- › Every method defined in the Object class is available in all objects in the system as all classes in the .NET Framework are derived from Object class.
- › Derived classes can override Equals, GetHashCode and ToString methods of Object class.
- › System.Object class is meant for achieving "type safety" in C#.
